Inhibiting miR-182-3p Alleviates Gestational Diabetes Mellitus by Improving Insulin Resistance in Skeletal Muscle

Jinghong Rao*, Youfang Chen*, Jingying Huang, Ruoying Wu, Zhenzhu Dong, Yuling Gao, Xuan Chen

Background: Gestational diabetes mellitus (GDM) is one of the most common metabolic diseases occurring during pregnancy. MiR-182-3p participates in a variety of physiological processes such as cell proliferation, apoptosis, differentiation, and migration, but its role in GDM is largely unknown.

Aims: To investigate the relationship between miRNA-182-3p and GDM and explore a potential therapeutic strategy for GDM.

Study Design: Animal experimentation

Methods: To evaluate the effect of miRNA182-3p in GDM, mice were separated as negative control (NC), miRNA-182-3p mimic or miRNA-182-3p inhibitor, and miRNAs were administered intraperitoneally. Additionally, miRNA-182-3p mimic or miRNA-182-3p inhibitor was transfected into C2C12 cells to evaluate glucose metabolism and insulin-related pathways.

Results: The miR-182-3p mimic accelerated GDM, which was effectively reversed by the inhibitor in GDM mice (P = 0.005, miR-182-3p inhibitor vs. mimic). Insulin receptor 1 (INSR1) was predicted to be the direct target gene of miR-182-3p using online tools. In addition, the miR-182-3p mimic inhibited INSR1 expression and insulin-related pathways in vivo and in vitro, which were all reversed by the miRNA82-3p inhibitor. Furthermore, the miR-182-3p mimic impaired glucose uptake and consumption by inhibiting translocation of glucose transporter type 4 (GLUT4) toward the C2C12 cell membrane (P = 0.007 vs. control), while the inhibitor accelerated these processes (P = 0.032 vs. control; P = 0.005, miRNA-182-3p inhibitor vs. mimic).

Conclusion: Inhibiting miR-182-3p effectively alleviated the development of GDM through INSR1, suggesting a potential therapeutic strategy for GDM.

INTRODUCTION

Gestational diabetes mellitus (GDM) is a condition in which a woman without diabetes develops glucose intolerance during the second or third trimester of pregnancy. GDM is a severe pregnancy syndrome, affecting 1-33% of pregnant women depending on the population, screening strategy, diagnostic method, and diagnostic thresholds. Insufficient insulin secretion from pancreatic beta cells does not meet the increased demand for insulin during the third trimester of pregnancy. Similar to cardiovascular disease, obesity, and type 2 diabetes mellitus (T2DM), the number of pregnant women with GDM is growing rapidly. Untreated GDM causes severe harm to the mother and fetus. Excessive blood glucose levels lead to malformations, dystocia, miscarriage, eclampsia, premature birth, and polyhydramnios. The insulin sensitivity of normal pregnant women decreases by about 60% during pregnancy and at the same time, their basal glucose production increases by about 30% to ensure the energy supply to the fetus. However, the balance between upregulated glucose production and downregulated insulin sensitivity is broken in patients with GDM, and insulin sensitivity decreases significantly in insulin-sensitive tissues, such as fat, muscle, and liver, leading to an imbalance in energy metabolism. The normal insulin response is destroyed, glucose uptake by the muscle tissue is reduced under insulin-induced conditions, and GDM develops.

Insulin resistance in skeletal muscle is related to many factors, including intramyocellular lipids, mitochondrial defects, the endocrine effects of adipokines, and inflammation. We focused on microRNA (miRNA). miRNA is a type of single-stranded small
Another set of normal pregnant mice was randomly divided into three groups with equal average body weight and injected with non-sense miRNA, miRNA-182-3p, or the miRNA-182-3p inhibitor twice per week. Their body weight was recorded on GD0, GD9, and GD18.

**Oral Glucose Tolerance Test (OGTT)**

Blood glucose was tested in all mice on GD15 after a 12-h fast, following oral administration of 2.0 g/kg aqueous glucose solution. Then, the blood glucose levels were examined after 30, 60, 90, and 120 min respectively. Blood glucose levels were recorded, and the area under the curve was analyzed according to a previous method.

**Dual-luciferase Reporter Assay**

An online database (https://cm.jefferson.edu/rna22/Interactive) was employed to predict the potential miR-182-3p targets as described previously, and to determine whether insulin receptor 1 (INSR1) was a direct target gene of miR-182-3p. Fragments of the synthetic INSR1 3’ untranslated region (UTR) (INSR-WT) containing potential binding sites and mutated potential binding sites of the INSR1 3’ UTR (INSR-Mu) were inserted into the pMIR-reporter plasmid using T4 DNA ligase after digestion with a restriction endonuclease. INSR-WT and INSR-Mut were co-transfected with the miR-182-3p mimic into HEK 293T cells (ATCC, Manassas, VA, USA) for 48 h. The cells were harvested, lysed, and centrifuged for 10 min. The supernatants were used to perform the luciferase assay using a luciferase assay kit (Promega, Madison, WI, USA) according to the manufacturer’s instructions. Luciferase activity was defined as RLUs of Renilla firefly luciferase/RLU.

**Transfection**

The mouse C2C12 muscle cell line (Chinese Academy of Sciences, Shanghai, China) was cultured in DMEM medium with 10% fetal bovine serum and transfected with the NC, the miR-182-3p mimic, and the miR-182-3p inhibitor using the Oligofectamine transfection reagent (Invitrogen, Waltham, MA, USA) for 48 h. The cells were harvested, lysed, and centrifuged. The supernatants were treated with a cocktail of protease inhibitors, and western blot was performed as described previously. The antibodies used are listed below:

GLUT4 (#2213), phospho-Akt (#8599), total-Akt (#9272S), phospho-AS160 (#4288), ERK1/2 (#9101S), phospho-ERK1/2 (#7670S), and INSR-1 (#2382S) were purchased from Cell Signaling Technology (Danvers, MA, USA) for 48 h. The treated cells were lysed in radioimmunoprecipitation buffer with a cocktail of protease inhibitors, and western blot was performed as described previously. The antibodies used are listed below:

GLUT4 (#2213), phospho-Akt (#8599), total-Akt (#9272S), phospho-AS160 (#4288), ERK1/2 (#9101S), phospho-ERK1/2 (#7670S), and INSR-1 (#2382S) were purchased from Cell Signaling Technology (Danvers, MA, USA) for 48 h. The cells were collected for further studies.

**Western Blot**

The treated cells were lysed in radioimmunoprecipitation buffer with a cocktail of protease inhibitors, and western blot was performed as described previously.

The antibodies used are listed below:

GLUT4 (#2213), phospho-Akt (#8599), total-Akt (#9272S), phospho-AS160 (#4288), ERK1/2 (#9101S), phospho-ERK1/2 (#7670S), and INSR-1 (#2382S) were purchased from Cell Signaling Technology (Danvers, MA, USA) for 48 h. The treated cells were lysed in radioimmunoprecipitation buffer with a cocktail of protease inhibitors, and western blot was performed as described previously.
treated cells, and qPCR was performed as described previously.11

Glucose Consumption
C2C12 cells were seeded in a 24-well plate. After transfection with non-sense miRNA, the miR-182-3p mimic, or the miRNA-182-3p inhibitor for 24 h, the medium was replaced with a low glucose medium containing 100 nM insulin for 12 h. The glucose concentrations in the culture medium were measured using a glucose assay kit. Glucose consumption = total glucose in blank wells – glucose in the culture medium.12

Glucose Uptake
Cells were seeded in 6-well plates. After transfection with non-sense miRNA, the miR-182-3p mimic, and the miRNA-182-3p inhibitor for 24 h, glucose uptake was determined using 2-NBDG as described previously.12 Briefly, treated cells were digested with trypsin and suspended in phosphate-buffered saline (PBS) with 1 μM insulin and 50 μM 2-NBDG for 30 min at 37 °C in the dark. After washing twice with pre-chilled PBS, the cells in PBS were analyzed by flow cytometry (Becton Dickinson, Franklin Lakes, NJ, USA). The mean fluorescence intensity served as the 2-NBDG uptake measure on a per-cell basis.

GLUT4 Translocation
GLUT4 translocation toward the plasma membrane was measured using a plasma membrane lawn assay as described previously.13 Briefly, after transfection with non-sense miRNA, the miRNA-182-3p mimic, or the miRNA-182-3p inhibitor for 24 h, the cells were starved in serum-free medium, and treated with insulin (100 nM). The cells were lysed by ultrasound with insulin (100 nM). The cells were lysed by ultrasound using an Astrason XL 2020 ultrasonic processor (Heat Systems-Ultrasonic, Farmingdale, NY, USA). After blocking, the lawns were incubated with anti-GLUT4 antibody at room temperature for 45 min followed by application of the secondary antibody (A488 conjugated donkey anti-goat IgG). The lawns were examined individually, and the fluorescence intensity of each cell was quantified using LSMS EXCITER-ZEN software (Zeiss Efficient Navigation, Carl Zeiss, White Plains, NY, USA) and shown as intensity per unit area. Data are presented as fold values relative to the control.

Statistical Analysis
The sample size was determined by a method described previously.1,2 According to this method, the power analysis showed that a sample size of at least six mice/group had a 90% power to detect a bodyweight change of 5 g on GD18, assuming a 5% significance level. Considering 20% attrition, eight mice in each group were needed. All data are expressed as mean ± standard deviation. The normality of the distribution of numeric parameters was tested with the Shapiro-Wilk test. The statistical analysis was carried out using ANOVA followed by the least-significant difference test to compare three means or Tukey’s Honestly Significant Difference test to compare six or more means. Repeated-measures ANOVA was also applied followed by the Bonferroni post-hoc test.

RESULTS
The miR-182-3p Inhibitor Alleviates GDM in GDM Mice
First, we examined the relative expression of circulating miR-182-3p in the normal pregnant and GDM mice during different stages of pregnancy. The expression of miR-182-3p was gradually enhanced during pregnancy and reached its highest level on GD 18 in the GDM mice. Compared to normal mice, the GDM mice displayed a significant increase in miR-182-3p expression during middle (GD9) (1.97 ± 0.58, P = 0.027) and late pregnancy (GD18) (3.02 ± 0.79, P = 0.003) (Figure 1a).

To evaluate the role of miR-182-3p in GDM, we injected non-sense miRNA, the miR-182-3p mimic, or the miR-182-3p inhibitor into GDM mice, and monitored their body weight during pregnancy, which is an important indicator of GDM. The body weight of GDM mice increased significantly on GD 0 compared to the normal group (22.4 ± 1.1 g, P < 0.001), confirming the occurrence of GDM (Figure 1b). Injecting the miR-182-3p mimic increased the body weight of GDM mice (P < 0.001) on GD 9, compared to the NC group, which decreased after injecting the miR-182-3p inhibitor (P = 0.003). However, no difference was observed between the NC group and the GDM + miR-182-3p inhibitor group. The mice in all groups gained weight continually during pregnancy, but mice in the GDM and NC groups gained more weight than the normal mice by GD 18. Mice injected with miR-182-3p further upregulated their body weight (P < 0.001), which was reversed by the miR-182-3p inhibitor (P = 0.004). Unlike on GD 9, the body weight of mice injected with miR-182-3p decreased significantly compared with the NC group (P = 0.006) (Figure 1b, 1c), suggesting that long-term treatment with the miR-182-3p inhibitor alleviated GDM.

To further investigate the role of miR-182-3p in GDM, we injected the miR-182-3p mimic and miR-182-3p inhibitor into normal pregnant mice and compared them to the normal group. Injecting miR-182-3p did not alter the body weight of pregnant mice, but mice injected with the miR-182-3p mimic gained significantly more weight than those in the normal group (24.5 ± 1.3 g, P = 0.036 at GD9; 29.3 ± 1.5 g, P = 0.007 by GD18) (Figure 1d). These data further indicate that miR-182-3p accelerated the occurrence of GDM and that inhibiting miR-182-3p alleviated GDM in GDM mice.

The miR-182-3p Inhibitor Improves Glucose and Insulin Tolerance in GDM Mice
Next, we performed the OGTT to test glucose tolerance in the GDM mice on GD 15. After a glucose gavage, blood glucose levels were significantly upregulated in all GDM mice compared to that in the normal group, and the blood glucose level increased the most in mice injected with the miR-182-3p mimic (P < 0.001). In contrast, the miR-182-3p inhibitor downregulated the blood glucose levels in GDM mice (P = 0.024). After 2 h of glucose gavage, the blood glucose level in normal pregnant mice returned to normal, while the levels in all other GDM mice remained high (Figure 2a). We analyzed the overall area under the GTT curve, and the data
showed that the miR-182-3p mimic aggravated glucose intolerance (37.2 ± 3.3 mM·h, \( P < 0.001 \)), whereas the miR-182-3p inhibitor improved glucose intolerance (21.6 ± 2.5 mM·h, \( P = 0.044 \)) in GDM mice (Figure 2b). In addition, the GDM mice displayed a higher fasting blood glucose level than that of the normal group (15.5 ± 3.1 mM/L, \( P < 0.001 \)), which is a symptom of GDM (Figure 2c). Not surprisingly, the miR-182-3p mimic induced higher blood glucose levels, which were reduced by the miR-182-3p inhibitor (\( P = 0.002 \)) (Figure 2c). Taken together, these data suggest that the miR-182-3p inhibitor improved glucose intolerance in GDM mice. Furthermore, we also measured fasting insulin levels and analyzed the HOMA-IR, which were consistent with the pattern of fasting glucose levels (Figure 2d, 2e). The miR-182-3p mimic further increased fasting insulin levels (0.82 ± 0.11 μg/L, \( P = 0.004 \)) and HOMA-IR (77.4 ± 8.4, \( P < 0.001 \)), which were ameliorated by the miR-182-3p inhibitor. These results indicate that the miRNA-182-3p inhibitor effectively improved insulin intolerance.

**INSR1 is a Direct Target of miR-182-3p**

We explored the miR-182-3p targets to further understand their role in GDM. First, we predicted the potential miR-182-3p targets in an online database as described previously and determined that INSR1 may be a target of miR-182-3p because it had potential binding sites in its 3’UTR with miR-182-3p (Figure 3a).

The dual-luciferase reporter gene assay was performed to verify whether INSR1 is a direct target gene of miR-182-3p. The luciferase assay showed that co-transfecting with miR-182-3p and INSR-WT inhibited the transcription of downstream genes (0.49 ± 0.07, \( P = 0.004 \)), whereas the reporter gene was expressed normally when we co-transfected with miR-182-3p and INSR-Mut (Figure 3b). These results indicate that miR-182-3p directly binds to INSR1 mRNA to inhibit it.

**miR-182-3p Impairs Insulin Signaling in C2C12 cells**

We speculated that miR-182-3p may regulate insulin signaling pathways, as miR-182-3p directly targeted the insulin receptor. In our study, we focused on skeletal muscle. First, we transfected non-sense miRNA, the miR-182-3p mimic, or the miR-182-3p inhibitor into C2C12 cells and examined INSR1 expression. The miR-182-3p mimic decreased INSR1 protein (0.45 ± 0.07, \( P = 0.006 \)) and mRNA levels compared to the NC (0.43 ± 0.10, \( P = 0.005 \)), which were induced by the miR-182-3p inhibitor (\( P = 0.004 \) and 0.035) (Figure 4a, 4b). Next, C2C12 cells were stimulated with insulin to activate downstream signaling pathways after 24-h of starvation. The cells were treated with non-sense miRNA, the miR-182-3p mimic, or the miR-182-3p inhibitor.
miR-182-3p Inhibits the Insulin Signaling Pathway In Vivo

To further confirm the inhibitory role of miR-182-3p on INSR1 and its downstream signaling pathways, we measured their expression in skeletal muscle of GDM mice. GDM reduced INSR1 protein expression (0.39 ± 0.04, P = 0.003) and deactivated insulin-related pathways, including Akt (0.28 ± 0.05, P = 0.003), AS160 (0.31 ± 0.06, P = 0.004), and ERK1/2 (0.52 ± 0.05, P = 0.006). All of these decreases were inhibited by the miR-182-3p mimic (0.18 ± 0.02, P = 0.038 for p-Akt; 0.27 ± 0.03, P = 0.019 for p-AS160; 0.33 ± 0.07, P = 0.024 for p-ERK1/2, vs. GDM group), and induced by the miR-182-3p inhibitor (0.32 ± 0.04, P = 0.027 for p-Akt; 0.67 ± 0.08, P = 0.008 for p-AS160; 0.65 ± 0.10, P = 0.042 for p-ERK1/2, vs. GDM group) (Figure 4c-4e). Taken together, miR-182-3p impaired the insulin-related signaling pathways in C2C12 cells.

The miR-182-3p inhibitor enhances insulin-stimulated GLUT4 translocation, as well as glucose uptake and glucose consumption in C2C12 cells.

Besides activating the downstream insulin pathways, INSR1 also regulates the translocation of glucose transporter type 4 (GLUT4) toward the plasma membrane. GLUT4 regulates glucose metabolism in skeletal muscle by facilitating glucose transport into cells when insulin binds to its ligands and activates downstream pathways.
We discovered that GLUT expression was not altered by either the miR-182-3p mimic or the inhibitor (Figure 6a). However, the miR-182-3p mimic significantly inhibited translocation of GLUT4 toward the plasma membrane (0.22 ± 0.03, P = 0.003), which was markedly reversed by the miR-182-3p inhibitor (1.25 ± 0.21, P<0.001 vs. miR-182-3p mimic group) (Figure 6b) in C2C12 cells. Consequently, glucose uptake (0.43 ± 0.06, P = 0.003) and glucose consumption (0.47 ± 0.09, P = 0.003) also decreased in response to miR-182-3p, which were both reversed by the miR-182-3p inhibitor in C2C12 cells (1.31 ± 0.05, P = 0.029 for glucose uptake; 1.27 ± 0.11, P = 0.005 for glucose consumption) (Figure 6c, 6d). These data demonstrate that miR-192-3p regulates glucose metabolism through GLUT4 in skeletal muscle.

**DISCUSSION**

This study investigated the role of miR-182-3p in GDM and discovered that the miR-182-3p inhibitor impaired GLUT4 translocation, glucose uptake, and glucose consumption by directly binding to INSR1 and inhibiting its expression as well as its downstream signaling pathways in skeletal muscle, including Akt, ERK1/2, and AS160. In contrast, the miR-182-3p inhibitor promoted GLUT4 translocation toward the plasma membrane, leading to upregulated glucose uptake and consumption by pathways. We discovered that GLUT expression was not altered by either the miR-182-3p mimic or the inhibitor (Figure 6a). However, the miR-182-3p mimic significantly inhibited translocation of GLUT4 toward the plasma membrane (0.22 ± 0.03, P = 0.003), which was markedly reversed by the miR-182-3p inhibitor (1.25 ± 0.21, P<0.001 vs. miR-182-3p mimic group) (Figure 6b) in C2C12 cells. Consequently, glucose uptake (0.43 ± 0.06, P = 0.003) and glucose consumption (0.47 ± 0.09, P = 0.003) also decreased in response to miR-182-3p, which were both reversed by the miR-182-3p inhibitor in C2C12 cells (1.31 ± 0.05, P = 0.029 for glucose uptake; 1.27 ± 0.11, P = 0.005 for glucose consumption) (Figure 6c, 6d). These data demonstrate that miR-192-3p regulates glucose metabolism through GLUT4 in skeletal muscle.

**DISCUSSION**

This study investigated the role of miR-182-3p in GDM and discovered that the miR-182-3p inhibitor impaired GLUT4 translocation, glucose uptake, and glucose consumption by directly binding to INSR1 and inhibiting its expression as well as its downstream signaling pathways in skeletal muscle, including Akt, ERK1/2, and AS160. In contrast, the miR-182-3p inhibitor promoted GLUT4 translocation toward the plasma membrane, leading to upregulated glucose uptake and consumption by
inducing INSR1 expression and activating insulin-stimulated signaling pathways in skeletal muscle. In addition, the miR-182-3p inhibitor improved glucose and insulin tolerance in GDM mice and reduced their body weight, indicating that the miR-182-3p inhibitor alleviated the progression of GDM in the GDM mice. Our study suggests that inhibiting miR-182-3p may be a promising strategy for treating GDM.

MicroRNA is a type of single-stranded non-coding RNA that participates in a wide range of physiological and pathological processes. Therefore, microRNAs have received widespread attention. miR-182 participates in several diseases. For example, miR-182 suppresses apoptosis of cardiomyocytes in non-ischemic heart failure.14 miR-182 inhibits kidney fibrosis by mediating the transforming growth factor beta1/smad3 signaling pathway.15 Moreover, miR-182 was discovered to be involved in the progression of several cancers, including ovarian carcinoma16, bladder cancer17,18, and non-small cell lung cancer.19 miR-182 is a promising biomarker of prostate cancer.20 miR-182-5p accelerates the progression of preeclampsia.21 A relevant study demonstrated that miR-182 promotes cardiac function in diabetic mice.22 Although no study has investigated the relationship between miR-182 and GDM, several miRNAs, including miR-182-3p, miR-122-5p, miR-132-3p, and miR-1323 have been evaluated in GDM patients by a case-control study.4 That study reported that miR-182-3p is differentially expressed in GDM patients, suggesting that miR-182-3p may be involved in GDM. Our current study determined for the first time that the miR-182 mimic accelerated GDM, and the miR-182 inhibitor effectively alleviated GDM.

GDM is the most common metabolic disease occurring during pregnancy and is caused by a decrease in maternal insulin sensitivity coupled with increased glucose production, leading to inadequate insulin response. Insulin resistance affects insulin-mediated carbohydrate, lipid, and protein metabolism, and is reflected by the rate of downregulated glucose uptake into major insulin-sensitive tissues, such as skeletal muscle, liver, and adipose tissue.23 Although it is still unknown whether insulin resistance...
occurs simultaneously in these insulin-sensitive tissues, our study targeted skeletal muscle, and we did not evaluate the role of miR-182-3p in other tissues, such as liver or adipose tissue, which may need further investigation.

GDM is a hyperglycemic state that occurs in pregnant women and is a complex pathophysiological process. Chronic inflammation is the leading cause of GDM. However, in our current study, we did not investigate whether the miR-182-3p inhibitor alleviated the progression of GDM by inhibiting the inflammatory response. No study has reported that miR-182-3p affects inflammation. In addition, for the first time, our study discovered that INSR1 is a direct target of miR-182-3p. Due to the importance of insulin in the development of GDM, we only focused on INSR1 and its downstream signaling pathways in our study, and we did not study the relationship between miR-182-3p and other GDM pathogenic factors.

The insulin receptor has two substrates, such as INSR1 and INSR2. INSR1 and INSR2 both bind to insulin and insulin-like growth factor to activate separate downstream signaling pathways. Mice lacking the INSR1 or INSR2 gene can develop diabetes. Although INSR1 and INSR2 share a similar mechanism with insulin, they act differently. Unlike INRS1, INRS2 has been rarely investigated. Therefore, considering our limited laboratory conditions, we only focused on INSR1, which is the direct target of miR-182-3p predicted by an online database.

Unlike other GLUTs, GLUT4 is an insulin-mediated glucose transporter. GLUT4 takes up glucose from the bloodstream in skeletal muscle, the heart, and fat. Here, INSR1 was the direct target of miR-182-3p and miR-182-3p affected the insulin signaling pathways and glucose metabolism, which is why we only investigated the insulin-relevant glucose transporter GLUT4, and not the other GLUTs.

Taken together, we discovered that the miR-182-3p inhibitor promoted GLUT4 translocation, as well as glucose uptake and consumption by increasing the expression of INSR1 and its downstream signaling pathways in skeletal muscle. Therefore, the miR-182-3p inhibitor alleviates the development of GDM, suggesting that inhibiting the miR-182-3p inhibitor could serve as a potential strategy for treating GDM.

**FIG. 6.** The miR-182-3p inhibitor enhances insulin-stimulated GLUT4 translocation toward the plasma membrane, as well as glucose uptake and consumption in C2C12 cells. (a) Effects of miR-182-3p on GLUT4 mRNA levels and protein expression in C2C12 cells. (b) GLUT4 translocation toward the plasma membrane was measured using the plasma membrane lawn assay. (c, d) Effects of miR-182-3p on glucose uptake (c) and glucose consumption (d) in C2C12 cells. Data are presented as mean ± SD of six independent experiments. **P < 0.01 for comparison with control. ###P < 0.001 between the miR-182-3p mimic group and the miR-182-3p inhibitor group.**
A strength of this study was the discovery that miR-182-3p directly binds to INSR1, which is a key regulator of insulin-related pathways. Considering the important role of INSR1 in the insulin pathway, the miR-182-3p inhibitor may be a promising therapy for GDM. However, the miR-182-3p mechanism was only explored in C2C12 cells, and we did not evaluate the effect of the miR-182-3p mimic or the miR-182-3p inhibitor in the muscle of GDM mice, which was a limitation. It will be necessary to evaluate the role of miR-182-3p in other insulin-related tissues, such as the liver, to further confirm the role of miR-182-3p in GDM.

In our study, we discovered that the miR-182-3p inhibitor promoted GLUT4 translocation, as well as glucose uptake and consumption by increasing the expression of INSR1 and its downstream signaling pathways in skeletal muscle. Therefore, the miR-182-3p inhibitor alleviated the development of GDM, suggesting that inhibiting the miR-182-3p inhibitor may be a potential strategy for treating GDM.
